

E-MAIL MANAGEMENT SYSTEM, MAIL SERVER, FORWARDING METHOD
AND MEDIUM

This is a continuation of Application PCT/JP01/01832, filed on March 8, 2001,
now abandoned.

5

BACKGROUND OF THE INVENTION

(Technical Field)

The present invention relates to a technology for
forwarding an E-mail.

10

(Background Arts)

An E-mail system has hitherto provided a forward
service for forwarding a received E-mail addressed to a
predetermined address. For utilizing this service, a user
15 registers beforehand a forward destination address
corresponding to a self-receipt address in a mail server.

Then, the mail server, when receiving the E-mail
addressed to this receipt address, forwards this E-mail
to the aforementioned forward destination. This scheme
20 enabled the user, when changing the E-mail address, to
separately use both of addresses before and after the
address change and to forward the E-mail to an E-mail
address used in home from an E-mail address used in a
workplace.

25 Thus, a forward function and a forward service of
the E-mail were convenient. It was, however, difficult
to confirm from only address information whether the

forward destination address is valid or not. In order to check validity of the forward destination address, there has hitherto been no alternative but to judge whether the forward destination address exists in, e.g., a
5 pre-registered list or not.

Moreover, if an erroneous mail delivery happens when forwarded to an off-office mail address from an in-office Intranet, there might be a case where enterprise confidential information leaks out. The conventional
10 list checking method was hard to prevent the erroneous mail delivery.

Further, if the mail address changes, the method of referring to the already-registered address list was impossible of judging the validity of the mail address.
15 Still further, once the forward destination address was registered, there was a case in which the unjustified forwarding continued even when the address thereafter became ineffective.

20 SUMMARY OF THE INVENTION

It is an object of the present invention, which was devised in view of the problems inherent in the prior arts, to provide a technology capable of automatically checking
25 validity of a forward destination address of an E-mail. The present invention aims at preventing an erroneous delivery of a forwarding mail in a way that permits

forwarding to the forward destination address with its validity confirmed.

The present invention further aims at preventing the E-mail from being forwarded without a limit of period
5 to the forward destination address that has once become effective.

To accomplish the above objects, the present invention adopted the following means.

An E-mail management system (1, 2) for managing a
10 forward destination of an E-mail according to the present invention, comprises an accept unit accepting a setting request of a forward destination address corresponding to a receipt address of the E-mail, and a confirming unit confirming a validity of the forward destination address.

15 Preferably, the aforementioned E-mail management system may further comprise a sending unit sending a test mail to the forward destination address, and a receiving unit receiving a response to the test mail, wherein the confirming unit may command the sending unit to send the
20 test mail and confirms a response via the receiving unit.

Preferably, the aforementioned E-mail management system (1) may further comprise an communication unit communicating with a sending device (4) sending the test mail to the forward destination and a receiving device
25 (2) receiving the response to the test mail, wherein the confirming unit may command the sending device (4) to send the test mail via the communication unit and may confirm

a response received by the receiving device (2) via the communication unit.

Preferably, the aforementioned E-mail management system (1, 2) may further comprise a forward destination
5 registering unit (5) registering the forward destination address if the confirmation proved successful, and a forward control unit (2) forwarding the E-mail, wherein the forward control unit (2), where the forward destination address corresponding to the receipt address is registered
10 in the forward destination registering unit, may forward the received E-mail addressed to this receipt address to the forward destination address.

Preferably, the aforementioned E-mail management system may further comprise an communication unit
15 communicating with a mail server (2) registering the forward destination address corresponding to the receipt address of the E-mail, and forwarding the received E-mail addressed to this receipt address to the forward destination address, wherein the confirming unit may
20 command, if the confirmation proved successful, the mail server (2) to register the forward destination address corresponding to the receipt address via the communication unit.

Preferably, the confirming unit may confirm whether
25 or not the response is transmitted from the receipt address.

Preferably, the confirming unit may give a command

of sending test mails respectively to the receipt address and the forward destination address, and may confirm responses to these two test mails.

Preferably, the forward destination registering
5 unit (5) may register a forward destination address unconditionally in response to a request for setting the forward destination address that is within a predetermined range, and may register a forward destination address
10 unit proved successful in response to a request for setting the forward destination address that is beyond the predetermined range.

Preferably, the E-mail management system (1, 2) may further comprise a notifying unit notifying that a
15 permission of forwarding to the forward destination address with respect to which the confirmation proved unsuccessful, can not be given.

Preferably, the confirming unit may confirm a
20 validity of the already-registered forward destination address after a predetermined period of time has elapsed since the registration thereof, and the forward control unit (2) may suspend forwarding to the forward destination address till the confirmation proves successful after the elapse of the predetermined period of time.

25 Preferably, the communication unit may receive a request for confirming the already-registered forward destination address from the mail server, and the

confirming unit may confirm the validity of this forward destination address.

Preferably, the E-mail management system may further comprise an information providing unit disclosing a step
5 of the response to the test mail, to a user who is within a predetermined range, wherein the confirming unit may confirm whether or not the response conforms with the response step.

Preferably, the confirming unit may confirm whether
10 the response contains a predetermined data string or not.

Further, an E-mail management system (1) according to the present invention, which cooperates with a mail server (2) registering a forward destination address corresponding to a receipt address of an E-mail and
15 forwarding the received E-mail addressed to this receipt address to the forward destination address, comprises an accept unit accepting a setting request of a forward destination address corresponding to a receipt address of the E-mail, and a command unit giving a command of
20 confirming a validity of the forward destination address.

Preferably, the E-mail management system may further comprise a sending unit sending a test mail to the forward destination, wherein the command unit may command the sending unit to send the test mail and may have a validity
25 of the forward destination address confirmed by a response to the test mail, to the mail server from the receipt address.

Preferably, the E-mail management system (1) may further comprise an communication unit communicating with a sending device (4) sending the test mail to the forward destination, wherein the command unit may command the sending device (4) to send the test mail to the forward destination address via the communication unit and has the validity of the forward destination address confirmed by the response to the test mail, to the mail server (2) from the receipt address.

Preferably, the sending device (4) may be the mail server (2).

Preferably, the command unit may give a command of sending test mails respectively to the receipt address and the forward destination address, and may make the mail server confirm the validity of responses to these two test mails.

Preferably, the communication unit may receive a request for confirming the already-registered forward destination address from the mail server, and the command unit may give the command of confirming the validity of this forward destination address.

Preferably, the E-mail management system (1) may further comprise an information disclosure unit disclosing a step of the response to the test mail, to a user who is within a predetermined range.

Preferably, the accept unit may accept the setting

request by receiving the E-mail in a predetermined format at a predetermined address.

Further, according to the present invention, a mail server (2) cooperating with an E-mail management system
5 (1) accepting a request for setting a forward destination address corresponding to a receipt address of an E-mail, comprises a confirming unit confirming a validity of the forward destination address, and a forward destination
10 registering unit (5, 8) registering the forward destination address corresponding to the receipt address of the E-mail, wherein the forward destination registering unit (5, 8) registers the forward destination address with its validity confirmed.

Preferably, the mail server (2) may further comprise
15 a receiving unit receiving a response to the test mail sent to the forward destination, wherein the confirming unit may confirm the validity of the forward destination address by the response.

Preferably, the confirming unit may confirm whether
20 the response is transmitted from the receipt address or not.

Preferably, the confirming unit may confirm whether the response contains a predetermined data string or not.

Moreover, an E-mail forward destination management
25 method of managing a forward destination of an E-mail according to the present invention, comprises accepting (106, S11) a request for setting a forward destination

address corresponding to a receipt address of an E-mail, and confirming (106, S23-S27) a validity of the forward destination address.

Further, according to the present invention, an
5 E-mail forward destination management method of managing a forward destination of an E-mail in cooperation with a mail server registering a forward destination address corresponding to a receipt address of the E-mail and forwarding the received E-mail addressed to this receipt
10 address to the forward destination address, comprises accepting (101, S11) a setting request of a forward destination address corresponding to a receipt address of the E-mail, and giving a command (102) of confirming a validity of the forward destination address.

15 Still further, according to the present invention, an E-mail forward destination management method of managing a forward destination of an E-mail in cooperation with an E-mail management system accepting a request for setting a forward destination address corresponding to
20 a receipt address of the E-mail, comprises confirming (106, S21-S23, S25-S27) a validity of the forward destination address, registering (S24) the forward destination address, and forwarding, when the forward destination address corresponding to an address of the E-mail
25 received is registered, the E-mail to this forward destination address.

Further, according to the present invention, there

may be provided a program for having any one of the
aforementioned functions actualized. Moreover,
according to the present invention, there may be provided
a readable-by-computer recording medium recorded with the
5 program described above.

As explained above, according to the present
invention, the E-mail forward function is capable of
automatically checking the validity of the forward
destination address. Then, according to the present
10 invention, the forwarding to the forward destination
address with its validity confirmed is permitted, and an
erroneous delivery of the forwarding mail is prevented.
Further, the present invention can prevent the E-mail from
being forwarded to the forward destination address that
15 has once become effective without a limit of period.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a diagram showing a system architecture
of an E-mail management system in a first embodiment of
20 the present invention;

FIG. 2 is a diagram showing a setting screen utilized
for receipt mail forward setting;

FIG. 3 is a diagram showing a display screen of
contents of the forward setting;

25 FIG. 4 is a diagram showing a display screen that
displays off-office forward setting steps of the receipt
mail;

FIG. 5 is a diagram showing an example of a test mail sent to an off-office forward destination address zzz@xxx.com from a Web server 1;

FIG. 6 is a diagram showing an example of a formatted
5 text C sent to a receipt mail server 2 from the Web server 1;

FIG. 7 is a diagram showing an example of a response mail sent by a user to the receipt mail server 2;

FIG. 8 is a diagram showing a data example of a forward
10 checklist 5 held by the receipt mail server 2;

FIG. 9 is a flowchart showing forward destination address setting steps;

FIG. 10 is a flowchart showing an effective period confirmation process executed by the receipt mail server
15 2;

FIG. 11 is a diagram showing a system architecture of the E-mail management system in a second embodiment;

FIG. 12 is a diagram showing an example of an E-mail sent to the receipt mail server 2 from a user terminal
20 3 when a forward setting request is made;

FIG. 13 is a diagram showing an example of a forward permission list 6;

FIG. 14 is a diagram showing an example of the E-mail sent to the user terminal 3 when the forward setting request
25 is approved;

FIG. 15 is a diagram showing an example of the E-mail set for obtaining contents of the present setting in a

forward setting file 8;

FIG. 16 is a flowchart showing a forward setting process executed by the receipt mail server 2; and

FIG. 17 is a flowchart showing details of a forward
5 permission list confirmation process.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Embodiments of the present invention will hereinafter be described with reference to the drawings.

10 <<First Embodiment>>

An E-mail management system according to a first embodiment of the present invention will hereinafter be explained in conjunction with FIGS. 1 through 10.

<System Architecture>

15 FIG. 1 is a diagram of a system architecture of this E-mail management system. This E-mail management system includes a user terminal 3 that transmits and receives mails, a transmission mail server 4 for managing transmissions of the mails, a receipt mail server 2 for
20 managing receipts of the mails, and a Web server 1 for accepting settings related the mail management.

The user terminals 3 and the respective servers configure an Intranet through a local area network (which will hereinafter be abbreviated to LAN). This Intranet
25 is connected to an external mail server on the Internet via a gateway to the outside.

The user terminal 3 is, for example, a personal

computer (which will hereinafter be abbreviated to PC).
The user terminal 3 provides the user with functions of
accessing the Web server, accessing the Internet, and
creating, transmitting, receiving and displaying the mail
5 and so forth. In FIG. 1, the user terminal 3 is assigned
a mail address such as user@ff.co.jp.

The transmission mail server 4 is a so-called server
device and includes an unillustrated CPU, memory, hard
disk, LAN board, etc.. The transmission mail server 4
10 is connected via the LAN board to the LAN, and manages
the transmissions of the E-mails (the LAN board corresponds
to an communication unit).

The E-mail to be transmitted is forwarded based on
SMTP (Simple Mail Forward Protocol) via the LAN to the
15 transmission mail server 4 from the user terminal 3, and
is forwarded to the mail server as a recipient. In FIG.
1, the transmission mail server 4 is assigned a domain
name such as smtp.ff.co.jp.

The receipt mail server 2 is a so-called server device
20 and includes an unillustrated CPU, memory, hard disk, LAN
board, etc.. The receipt mail server 2 is connected via
the LAN board to the LAN, and manages the receipts of the
E-mails (the LAN board corresponds to an communication
unit).

25 The E-mail received is read based on POP (Post Office
Protocol) to the user terminal 3. In FIG. 1, the receipt
mail server 2 is assigned a domain name such as

pop.ff.co.jp.

This receipt mail server 2 provides a mail forward function of forwarding the delivered user-addressed mail to other mail address designated by the user (the CPU of
5 the receipt mail server 2 providing this function corresponds to a forward control unit).

Therefore, the receipt mail server 2 has a forward destination checklist 5 contained in a file within the unillustrated hard disk. The forward destination
10 checklist 5 is a file in which a mapping between a receipt address of the E-mail and a forward destination address of the received E-mail addressed to the receipt address, is defined.

Further, the receipt mail server 2 receives from
15 the user terminal 3 a reply to a test mail sent to its forward destination address (the CPU and the LAN board of the receipt mail server 2 providing this function correspond to a receipt unit). Then, the receipt mail server 2 judges a validity of the reply and stores the
20 forwarddestinationchecklist5withaforwarddestination address of the reply judged to be valid (the CPU of the receipt mail server 2 providing this function corresponds to a confirming unit).

The Web server 1 is also a so-called server device
25 and includes an unillustrated CPU, memory, hard disk, LAN board, etc.. The Web server 1 is connected via the LAN board to the LAN (the LAN board corresponds to an

communication unit). The Web server 1 provides based on HTTP (HyperText Forward Protocol) the user terminal 3 with a variety of setting screens and messages via the LAN.

For instance, the Web server 1 provides a Web page
5 for utilizing the mail forward function. The user has this Web page displayed on the user terminal 3 and inputs or changes the forward destination address, etc..

Moreover, the Web server 1 sends a test mail for checking the validity of the mail address of the forward
10 destination that is set in the Web page described above (the CPU and the LAN board of the Web server 1 providing this function correspond to a transmission unit). Further, the Web server 1 provides the user with information representing response steps for responding to the test
15 mail. This item of information is described by HTML (HyperText Markup Language) and stored on the unillustrated hard disk (the CPU and the hard disk of the Web server 1 executing this process correspond to an information providing unit).

20 <Outline of Functions>

According to the present invention, the forward destination address is set on the Web page on the Web server 1. This Web server 1, when the forward destination address (e.g., a mail address, etc. within the same place of duty)
25 permitting the forwarding unconditionally is applied for, enables the E-mail to be immediately forwarded to this forward destination address. Therefore, the Web server

1 notifies the receipt mail server 2 of this forward destination address.

When the user inputs a forward destination address, for instance, an off-office address that does not
5 unconditionally permit the forwarding, the Web server 1 sends the test mail containing a predetermined keyword (which will hereinafter be referred to as a keyword 2).

Details of a method of replying to this test mail are described on the Web page provided by the same Web
10 server 1. If the reply to a specified address meets predetermined requirements, the receipt mail server 2 admits that the forward destination address is valid. Then, the receipt mail server 2 validates this forward destination address and registers it in the forward
15 destination checklist 5. Through this arrangement, the receipt mail server 2 permits the forwarding to that forward destination address.

Herein, the predetermined requirements are that the reply is sent from the predetermined mail address (such
20 as the in-office mail address, etc.), that the reply is described in a formatted-text form displayed on the Web page, and that the reply contains a keyword 1 written on the Web page and the keyword 2 written in the test mail. Further, if the contents of the reply do not meet these
25 conditions, the forwarding to that address is not permitted.

The receipt mail server 2 sets an effective period

for the effective forward destination address and, after a fixed period of time, automatically resends the test mail. If a reply to this test mail meets the predetermined requirements, the receipt mail server 2 prolongs the
5 effective period.

If there is no reply for the fixed period of time, however, or if that reply does not meet the predetermined requirements, the receipt mail server 2 deletes that forward destination address from the forward destination
10 checklist 5. The forwarding to that forward destination address is thereby inhibited.

<Screen Layout>

FIGS. 2 through 4 show setting screens provided based on HTTP to the user terminal 3 from the Web server 1 (the
15 CPU of the Web server 1 providing this function corresponds to an accepting unit). These screens are provided to the user terminal 3 from the Web server 1 in the Intranet.

Therefore, a host (a third party) on the Internet is unable to access these screens. FIG. 2 shows the setting
20 screen used for setting a forward of the receipt mail to an in-office address or an affiliated company.

This screen contains a mail server designation box 11, a mail address designation box 12, a password designation box 13, a forward destination address
25 designation box 14, a forward-to-the-source-of-forward designation box 15, a "set" button, and a "cancel" button.

The domain name of the receipt mail server 2 is

designated in the mail server designation box 11. This receipt mail server 2 manages the mails to be forwarded. Referring to FIG. 2, the domain name "pop.ff.co.jp" is designated as the receipt mail server 2.

5 The user's receipt mail address is designated in the mail address designation box 12. This address is also called a forward source address. A user account (which is "user" in FIG. 2) excluding a domain "@ff.co.jp" is designated in the mail address designation box 12.

10 A password used when the user terminal 3 accesses the receipt mail server 2, is designated in the password designation box 13.

 A forward destination address used for forwarding the received E-mail addressed to the forward source address, 15 is designated in the forward destination address designation box 14. On the setting screen in FIG. 2, however, only the forwarding to the in-office address or the affiliated company is permitted. When putting a checkmark in the forward-to-the-forward-source 20 designation box 15, the forward source itself is contained in the forward destination address.

 After the settings described above, when the user presses the "set" button by use of an unillustrated pointing device on the user terminal 3, the contents set 25 on this screen are set in the forward destination checklist 5 shown in FIG. 1. Further, when pressing the "cancel" button, the contents set on the screen in FIG. 2 are

discarded.

FIG. 3 shows a screen for displaying the contents of the forward setting. This screen is utilized when displaying the contents of the forward destination address setting. This screen contains, as on the setting screen in FIG. 2, the mail server designation box 11, the mail address designation box 12 and the password designation box 13. Further, this screen contains a "display" button and the "cancel" button.

10 A domain name of the mail server that retains the contents of the forward setting is designated in the mail server designation box 11. Further, a mail address of the forward source is designated in the mail address designation box 12. Moreover, as in the case shown in
15 FIG. 2, a password used when the user terminal 3 accesses the mail server is designated in the password designation box 13.

After the settings described above, when the user presses the "display" button, the setting contents of the forward destination address mapping to the forward source address designated in the mail address designation box 12 are displayed. Further, when the user presses the "cancel" button, the setting contents in FIG. 3 are discarded.

25 FIG. 4 shows a screen for displaying forward setting steps of forwarding the receipt mail to an off-office address.

This screen contains a description display area 16 and a test mail sending area 17. The description display area 16 displays a test mail sending request step for checking a validity of the forward destination, and a step
5 for responding to the test mail.

The user, after reading the description in the description display area 16, makes a request for sending the test mail in the test mail sending area 17. The test mail sending area 17 contains a mail server designation
10 box 11, an in-office mail address designation box 12A, a forward destination address designation box 14A, the "send" button and the "cancel" button.

As in the case shown in FIG. 2, the domain name of the receipt mail server 2 is designated in the mail
15 server designation box 11. Further, as in the case of the mail address designation box 12 in FIG. 2, the forward source mail address is designated in the in-office mail address designation box 12A. Moreover, an off-office forward destination mail address is designated in the
20 forward destination mail address designation box 14A.

After the settings described above, when the user presses the "send" button, the Web server 1 sends the test mail to the in-office E-mail address designated in the in-office mail address designation box 12A and to the
25 forward destination address designated in the forward destination mail address designation box 14A.

At this time, the Web server 1 sends a formatted

text C for making a request for the forward permission to the receipt mail server 2 designated in the mail server designation box 11 (the CPU of the Web server 1 executing this process corresponds to a command unit).

5 Upon receiving the formatted text C, the receipt mail server 2 adds the aforementioned forward destination address to the forward destination checklist 5 shown in FIG. 1. In this case, however, the forward destination address is set in a wait-for-confirmation status, wherein
10 the received mail is not actually forwarded to that address.

 The user, when receiving this test mail addressed to the in-office E-mail address and to the forward destination address, sends responses to the respective
15 test mails in accordance with the steps in the description display area 16. When the mail server receives these two responses and confirms the validity thereof, the receipt mail server 2 sets, in a forward permission status, the forward destination address that has been set in the
20 wait-for-confirmation status in the forward destination checklist 5. With this setting, the forward destination address becomes effective, and the receipt mail is forwarded to the forward destination address thereof.

<Data Structure>

25 FIG. 5 shows an example of the test mail sent to an off-office forward destination address
"zzz@xxx.com" from the Web server 1. This test mail

contains a title and a test.

In the test mail, the title is set such as "mail test". Further, a keyword 2 consisting of random numbers and a forward destination address effective period
5 "20010320 (March 20th in the year of 2001) are described in the "text".

Note that an E-mail having the same contents as those of this test mail is sent to the normal in-office E-mail address (that is the E-mail address designated in the
10 in-office mail address designation box 12A in FIG. 4).

FIG. 6 shows an example of a formatted text C sent to an accept address fwcheck@ff.co.jp of the receipt mail server 2 from the Web server 1. This E-mail is termed a forward permission request mail. The forward permission
15 request mail contains a title, a sender and a text.

In the forward permission request mail, the title is set such as "forward check". An E-mail address of a user who utilizes the forward function is described in the "sender". Further, "a character string such as
20 "forward checklist", an e-mail address of the user utilizing the forward function, a forward destination E-mail address, a keyword 2 consisting of the random numbers, a forward destination address effective period and a reply effective period, are described in the "text".

25 Herein, the forward destination address effective period is an effective period of the forward destination address, which is set within a predetermined allowable

range by the user. On the other hand, the reply effective period is a reply effective period set based on a system parameter in the Web server 1. Even if the user replies to the test mail after this reply effective period, the
5 mail forwarding is not permitted.

FIG. 7 shows an example of a response mail sent by the user to a response receipt address forward-append@ff.co.jp of the receipt mail server 2 from an E-mail address user@ff.co.jp.

10 The user, when receiving the test mail addressed to the normal in-office E-mail address (that is the E-mail address designated in the in-office mail address designation box 12A in FIG. 4) and to the forward destination address, sends a response mail to the test
15 mail to the accept address forward-append@ff.co.jp of the receipt mail server 2. FIG. 7 shows an example of the response sent by the user from the normal in-office E-mail address.

This response mail contains a title, a text, a name,
20 an assignment place, a forward destination, a reason for forwarding, a keyword 1, a keyword 2 and an effective period. A structure of such a response mail is clarified on an off-office forward setting step screen (FIG. 4) provided by the Web server 1.

25 In this response mail, the title is set such as forward-append@ff.co.jp. Further, "Give the permission of the forward setting" is described in the "text". The

name is a name of the user who registered the forward destination address, and the assignment place is the place to which the user is assigned. The forward destination is an off-office forward destination mail address to which
5 the received mail is forwarded.

Further, the keyword 1 is what is set on the off-office forward setting step screen (FIG. 4) provided by the Web server 1. Moreover, the keyword 2 is what is designated in the "text" of the test mail sent to the forward
10 destination address from the Web server 1. Further, the forward destination address effective period is an effective period for which the forwarding of the E-mail is permitted.

FIG. 8 shows an example of data of the forward
15 destination checklist 5 held by the receipt mail server 2. This forward destination checklist 5 is set for every user receiving a service of the receipt mail server 2. The forward destination checklist 5 is such that a user name is designated in a first line. Further, designations
20 of the forward destinations are listed up in second and consecutive lines.

Each line for the designation of the forward destination contains a forward destination address, a status, a keyword 2 and a forward effective period.
25 Further, a comment is subsequent to a character "#" in each line. The status among these elements defines a status of availability of each forward destination

address.

For instance, when the status is OK, this implies that an E-mail forward service to the forward destination address is being performed.

5 Moreover, when the status WT, this implies that the receipt mail server 2 receives the forward permission request mail from the Web server 1, and the forward destination address thereof is in the process of being checked by the test mail. Alternatively, the WT status
10 may also imply that the effective period of the forward destination address expires, and the forward destination address thereof is in the process of being checked by the test mail.

 Further, in the case of NG, this implies a status
15 where the forward destination address thereof is unusable. This is the forward destination address of which a use suspension is designated by the user through an unillustrated user interface. Thus, the user can select and use a desired address among the plurality of forward
20 destination addresses registered in the forward destination checklist 5, and can suspend the use of those other than selected address.

 For example, in the second line of the forward destination checklist 5 shown in FIG. 8, a forward
25 destination address xxx@nif.com is designated, and the status is OK. Accordingly, the user-addressed E-mail arrived at the present is forwarded to xxx@nif.com. The

effective period of this forward destination address is set on February 28, 2001.

Further, in the third line, a forward destination address yyy@ppp.com is designated, and the status is NG.
5 Accordingly, the received E-mail is not forwarded to this forward destination address at the present.

Moreover, in the fourth line, a forward destination address zzz@xxx.com is designated, and the status is WT, i.e., the wait-for-confirmation status. Hence, when the
10 response mail to the test mail with respect to this forward destination address is normally received, this forward destination address is used.

<Operation and Effect>

FIG. 9 shows forward destination address setting
15 steps in the present E-mail management system. Now, the Webpage of the Web server 1 is displayed on the user terminal 3 as the user operates.

The user terminal 3 receives inputs of a user name, a mail address, a forward destination address, etc. on
20 this Web page. These inputs are transmitted via the LAN to the Web server 1 (an arrowhead 101).

If the forward destination address is within the allowable range, the Web server 1 immediately sends a setting file describing the forward destination address
25 to the receipt mail server 2. Herein, the setting file is a file describing a name of the user making a request for the forward setting, a forward destination address

thereof and a forward destination address effective period.

Whereas if the forward destination address is beyond the allowable range, the Web server 1 sends a test mail
5 A containing the designated keyword 2 to the forward destination address. Further, the Web server 1 sends a test mail B containing the designated keyword 2 to the normal receipt mail address (the forward source mail address). Moreover, the Web server 1 embeds the forward
10 destination information of the user in the form of the formatted text C and thus forwards the same information to the receipt mail server 2 (an arrowhead 102).

This formatted text C contains a normally-used mail address of the user, a forward destination address, a
15 keyword 2, a forward destination address effective period and a reply effective period. The receipt mail server 2 saves the user's forward destination information as an un-illustrated temporary file 7 (Refer to the second embodiment).

20 Then, the test mail A sent as above is received by the user terminal 3 from the forward destination mail address (an arrowhead 103). Further, the test mail B is received by the user terminal 3 from the normal receipt mail address (an arrowhead 104). Note that the terminal
25 receiving these test mails A, B may not be the same.

A Web page reply step and a reply illustrative sentence D are displayed on the user terminal 3 (an

arrowhead 105), and the user refers to the reply step and the reply illustrative sentence D. Further, this reply step explicitly contains the keyword 1 (see FIG. 4). With reference to the reply illustrative sentence D, the user
5 adds the name, the assignment place and the keyword 1 to the contents of the received test mail A, thereby creating a reply mail X to the test mail A. Further, with reference to the reply illustrative sentence D, the user adds the name, the assignment place and the keyword 1 to the contents
10 of the received test mail B, thereby creating a reply mail Y to the test mail B.

Then, the user sends, to the receipt mail server 2, the reply mails X and Y with the titles designated in the formatted text which is shown in the web page from
15 the normal mail address (the forward source address) and the forward destination address (an arrowhead 106).

The receipt mail server 2 confirms whether or not the reply mails X and Y have been received within the reply effective periods. Then, when the reply mails X and Y
20 have been received within the reply effective periods, the receipt mail server 2 confirms whether or not the keywords 1 are contained in the reply mails X and Y. Note that the keyword 1 is a piece of information set as a constant in the Web server 1 and in the receipt mail server 2.

25 If these reply mails contain the keywords 1, the receipt mail server 2 can confirm that the reply mails are based on the off-office forward setting step (FIG.

4). Such being the case, next, the receipt mail server 2 collates the reply mails X and Y with the formatted text C.

Then, if both of the reply mails X (containing the
5 keyword 2) and Y (containing the keyword 2) are matched with the content of the formatted text C (containing the keyword 2), the receipt mail server 2 adds the forward destination address concerned to the forward destination checklist 5 in the OK-status.

10 Further, simultaneously, the receipt mail server 2 sets the effective period of that forward destination address in the forward destination checklist 5. Then, the receipt mail server 2 deletes the formatted text retained in the temporary file 7.

15 While on the other hand, if the keyword 1 is contained in the reply mail X or the reply mail Y in the step described above, these reply mails are each judged not to be a valid reply that conforms to the off-office forward setting step (FIG. 4).

20 Further, even if the reply mail X or Y contains the keyword 1, unless the reply mail X or Y is matched with the contents of the formatted text C (such as a case where the keyword 2 is not contained, and so on), the receipt mail server 2 judges this reply mail not to be the valid
25 reply mail.

In these cases, the receipt mail server 2 does not set the forward destination address in the forward

destination checklist 5. Then, the receipt mail server 2 deletes the formatted text C retained in the temporary file 7.

FIG. 10 shows an effective period check process
5 executed by the receipt mail server 2. This process is periodically started up in the receipt mail server 2, thereby executing a management of the period of the forward destination address.

In this process, to begin with, the receipt mail
10 server 2 reads a next forward destination designated line, where OK-status is designated, from the forward destination checklist 5 (S1). Subsequently, the receipt mail server 2 judges whether the forward effective period contained in that forward destination designated line is
15 a predetermined date anterior to a expiration or not (S2).

If the forward effective period is a predetermined date anterior to the expiration, the receipt mail server 2 sends the test mail to the forward destination thereof (S3). Thereafter, the receipt mail server 2 advances the
20 control to a judgement in S6. Note that a response to this test mail is processed in the same step as explained in FIG. 9.

Whereas if judged in S2 not to be anterior to the predetermined expiration date, the receipt mail server
25 2 judges, from whether the forward effective period elapses over the present date, whether this effective period expires or not (S4). Then, if it expires, the receipt

mail server 2 deletes that forward destination designated line from the forward destination checklist 5.

With this processing, the receipt mail server 2 stops the forward service for that forward destination address (S5). Thereafter, the receipt mail server 2 makes the control proceed to a judgement in S6. Further, if it is judged in S4 that the effective period does not yet expire, the receipt mail server 2 skips over that forward destination designated line and advances the control to the judgement in S6.

Next, the receipt mail server 2 judges whether a next forward destination designated line exists in the forward destination checklist 5 (S6). If there is the next forward destination designated line, the receipt mail server 2 returns the control to S1. Whereas if next forward destination designated line does not exist, the receipt mail server 2 terminates the process.

As discussed so far, according to the present E-mail management system, the validity of the forward destination address is checked by the E-mail forward function of the receipt mail server 2. Namely, the test mail is sent to the forward destination address and, if the valid reply mail to the test mail is sent back to the receipt mail server 2, the forward destination address becomes effective. Therefore, the processing by the receipt mail server 2 enables the setting of a wrong forward destination to be prevented.

Moreover, the receipt mail server 2 confirms, as the conditions for the validity, that the response to the test mail is given from the forward destination address, and besides that the response to the test mail is given
5 from the normally used mail address. It is therefore possible to make the forward requester respond to the test mail by use of the E-mail address managed beforehand. Hence, an unjustified response to the test mail can be prevented.

10 Further, the Web server 1 in the first embodiment discussed above, if the forward destination address of which the forward setting is requested on the Web page falls within the predetermined range, e.g., the range covering the in-office addresses and the addresses of the
15 affiliated companies, immediately makes the receipt mail server 2 register this forward destination address. On the other hand, the test mail is delivered to the off-office forward destination address. Therefore, the in-self-office forward destination addresses can be
20 quickly registered. While on the other hand, the off-self-office forward destination addresses of the E-mails can be strictly checked.

Moreover, the receipt mail server 2 retains the forward destination address effective period in each
25 forward destination designated line of the forward destination checklist 5. It is therefore feasible to prevent the E-mail from being forwarded to the forward

destination address beyond the period. Moreover, the forward effectiveness or ineffectiveness can be freely set within the period range described above.

Further, according to the first embodiment, the
5 response step to the test mail is provided from the Web server 1 on the Intranet. Accordingly, an external third party posing as the party concerned can be prevented from responding to the test mail.

<Modified Example>

10 In the first embodiment, the test mail A is sent to the forward destination address, and the test mail B is sent to the normally used forward source mail address. The embodiment of the present invention is not, however, limited to the scheme and steps described above. For
15 example, the test mail A is sent to the forward destination address, while the test mail B may not be sent to the normally used forward source mail address. Namely, the validity of the forward destination address may be checked by only the test mail addressed to the forward destination address.

20 According to the first embodiment, the Web server 1 providing the Web page on which the application for the forward destination address is received, sends the test mail to the forward destination address. Further, the Web server 1 sends the formatted text C for making the
25 request for the permission of forwarding to the receipt mail server 2. The embodiment of the present invention is not, however, confined to the scheme and steps described

above.

For instance, the Web server 1 may request other communication device to send the test mail. Moreover, the Web server 1 may send the formatted text C for making
5 the request for the permission of forwarding to the receipt mail server 2, and may also request this receipt mail server 2 to send the test mail (in this case, the receipt mail server 2 corresponds to a communication device). At this time, communications between the Web server 1 and the
10 receipt mail server 2 may be performed by the E-mails or by utilizing other file forward functions such as FTP (File Transfer Protocol), etc. and a file sharing function based on NFS (Network File System), etc..

In this case, the receipt mail server 2 and the
15 transmission mail server 4 may be operated based on the same host. Further, the Web server 1 and the receipt mail server 2 may be operated based on the same host. In this case, the receipt mail server 2 may execute accepting the forward setting request, sending the test mail, confirming
20 the response to the test mail, registering the forward destination address after confirming the response, and so forth.

Reversely, these processes such as accepting the forward setting request, sending the test mail, confirming
25 the response to the test mail, registering the forward destination address after confirming the response and so on, may also be shared among different server devices.

In this case, the communications among the servers may involve utilizing the aforementioned E-mails, FTP, NFS, or RPCs (Remote Procedure Calls) that are well known in, e.g., the UNIX system and DCOM (Distributed Component
5 Object Model) provided as a Windows function which is defined as OS of the Microsoft Corp., U.S.A..

According to the first embodiment, the keyword 1 is fixedly set as the value of constant in the Web server 1 and the receipt server 2. As a substitute for this,
10 however, the keyword 1 may be transferred to the receipt mail server 2 from the Web server 1. It may suffice for attaining this to have the keyword 1 contained in the formatted text C (FIG. 6) sent to the receipt mail server 2 from the Web server 1.

15 <<Second Embodiment>>

A second embodiment of the present invention will be discussed with reference to FIGS. 11 through 17. The first embodiment has exemplified the E-mail management system in which the Web page for setting the forward
20 destination address is provided, and the user is made to set the forward destination address on the basis of the information on this Web page.

The second embodiment will exemplify an E-mail management system for setting the forward destination
25 address by sending an E-mail to the receipt mail server 2 from the user terminal 3 without utilizing the Web server 1 described above. Other configurations and operations

are the same as those in the first embodiment. Such being the case, the same components are marked with the same symbols as those in the first embodiment, and their explanations are omitted. Further, the drawings in FIGS. 1 through 10 will be referred to when the necessity may arise.

<System Architecture>

FIG. 11 is a diagram showing a system architecture of the E-mail management system in the second embodiment. This system includes the user terminal 3 utilized by the user and the receipt mail server 2. The user terminal 3 and the receipt mail server 2 are connected via the LAN to each other. Further, this system is connected to the Internet via a gateway to the outside.

In the second embodiment, the receipt mail server 2 has a forward permission list 6, a temporary file 7 and a forward setting file 8. In the receipt mail server 2, the forward permission list 6 is registered with one or more forward destination addresses permitted to receive the E-mails forwarded.

The forward setting file 8 is registered with a forward destination address to which the received E-mail is forwarded. The user can register the forward destination in the forward setting file 8 by sending an E-mail for making a request for a forward setting to an accept address (fwset@ff.co.jp) of the receipt mail server 2.

The temporary file 7 is buffered with a content of such an E-mail for making the forward setting request given from the user. When the forward destination of which the forward setting is requested by the user proves permitted
5 in the forward permission list 6, this forward destination is transferred to the forward setting file 8 from the temporary file 7.

On the other hand, if the forward destination of which the forward setting is requested by the user is not
10 registered in the forward permission list 6, the receipt mail server 2 sends the test mail to the forward destination in the same steps as those done by the Web server 1 in the first embodiment.

Then, in the same steps as in the case of the first
15 embodiment, just when the response to the test mail is confirmed, the forward destination address is added to the forward permission list 6 and further registered in the forward setting file 8. The forward setting request is retained in the temporary file 7 till the response to
20 the test mail is confirmed.

<Data Structure>

FIG. 12 shows an example of the E-mail delivered to the receipt mail server 2 from the user terminal 3 when making the forward setting request. The user desiring
25 to forward the E-mail received sends the E-mail shown in FIG. 12 to the accept address (fwset@ff.co.jp in FIG. 12) of the receipt mail server 2.

In the E-mail in FIG. 12, a title "forward-set" represents that this E-mail is the forward setting request. Further, "set forward list" described in the first line of the text represents that the forward destination
5 addresses are listed up in the lines under the first line. The embodiment of the present invention is not, however, limited to the aforementioned title and the text description itself.

Further, in the E-mail shown in FIG. 12,
10 aaa@ff.co.jp, etc. is defined as the forward destination address. Moreover, Yuser in the last line designates a registration of a forward source address itself in the forward destination.

FIG. 13 shows an example of the forward permission
15 list 6. The forward permission list 6 is created for every user. A user name defined as a recipient of the E-mail to be forwarded is described in the first line of the forward permission list 6.

Further, in the forward permission list 6, a
20 permitted forward destination address and a permission effective period are listed up subsequently to the description of the user name. For example, *@ff.co.jp is a designation that permits forwarding to all the in-office addresses. Namely, forwarding to all the
25 addresses having the domain name "ff.co.jp" is permitted. Referring to FIG. 13, the period for the in-office address is set to an "indefinite period".

Referring again to FIG. 13, for instance, bbb@nif.com 20010630 implies that forwarding to the forward destination address bbb@nif.com is permitted till June 30th, 2001.

5 FIG. 14 shows an example of the E-mail delivered to the user terminal 3 from the receipt mail server 2 when the forward destination address is registered in the forward setting file 8 upon an approval of the forward setting request. Note that if the forward setting request
10 is not approved, the receipt mail server 2 may notify the user terminal 3 of the request's being unapproved. The CPU of the receipt mail server 2 executing such a process corresponds a notifying unit.

 In this E-mail a title "forward-changed" represents
15 that the forward setting request is approved, and the forward destination has been changed. A text thereof contains a registration completed date/time of the forward destination, a message indicating that the forward destination has been changed, and setting contents of the
20 forward setting file 8 of the user concerned after the change.

 FIG. 15 shows an example of an E-mail sent in order for the user to obtain the present setting contents of the forward setting file 8. When the user terminal 3 sends
25 the E-mail shown in FIG. 15 to the receipt mail server 2, the receipt mail server 2 replies the setting contents of the forward setting file 8 to the user concerned.

In this E-mail, a title is "forward-get" that implies a reply request of the setting contents of the forward setting file 8. Further, "get-forward-list" in the text implies that this E-mail is a reply request of the setting contents of the forward setting file 8. Moreover, a target user is designated next to this "get-forward-list" line.

<Operation and Effect>

FIG. 16 shows a flowchart of a forward setting process executed by the receipt mail server 2. This process is started up when receiving the E-mail addressed to the accept address (fwset@ff.co.jp in FIG. 11) of the receipt mail server 2. In this process, the receipt mail server 2, at first, reads the forward setting request E-mail (S11).

Next, the receipt mail server 2 stores contents of this E-mail in the temporary file 7 (S12). Subsequently, the receipt mail server 2 executes a forward permission list confirmation process (S13).

FIG. 17 shows details of the forward permission list confirmation process. In this process, the receipt mail server 2, to begin with, reads a next forward destination from the temporary file 7 (S21). Next, the receipt mail server 2 confirms the forward permission list 6 (S22). Then, the receipt mail server 2 judges whether or not a forward destination address thereof is contained in the forward permission list 6 (S23).

If the forward destination is contained in the

forward permission list 6, the receipt mail server 2 transfers this forward destination to the forward setting file 8 from the temporary file 7 (S24). Thereafter, the receipt mail server 2 advances the control to a process
5 in S26.

Whereas if the forward destination is not contained in the forward permission list 6, the receipt mail server 2 sends the test mail to this forward destination (S25). Upon a confirmation of a response to this test mail, the
10 forward destination is registered in the forward permission list 6 and further set in the forward setting file 8. The step of confirming the response to the test mail is the same as in the first embodiment, and hence its explanation is omitted.

15 Next, the receipt mail server 2 judges whether or not a next forward destination exists in the temporary file 7 (S26). If the next forward destination is left in the temporary file 7, the receipt mail server 2 returns the control S21. Whereas if the next forward destination
20 is not left in the temporary file 7, the receipt mail server 2 sends a change notifying mail to the user (S27). Thereafter, the CPU 2 terminates the process.

As discussed above, according to the second embodiment, unlike the first embodiment the forward
25 setting can be managed only by sending and receiving the E-mail without utilizing the Web server 1.

<<Readable-by-Computer Recording Medium>>

The program executed in the Web server 1 or the receipt mail server 2 in the embodiments discussed above can be recorded on a readable-by-computer recording medium. Then, the computer reads and executes the program on this
5 recording medium, thereby functioning as the Web server 1 or the receipt mail server 2 shown in the embodiments discussed above.

Herein, the readable-by-computer recording medium includes recording mediums capable of storing information
10 such as data, programs, etc. electrically, magnetically, optically and mechanically or by chemical action, which can be all read by the computer. What is demountable out of the computer among those recording mediums may be, e.g., a floppy disk, a magneto-optic disk, a CD-ROM, a CD-R/W,
15 a DVD, a DAT, an 8mm tape, a memory card, etc..

Further, a hard disk, a ROM (Read Only Memory) and so on are classified as fixed type recording mediums within the computer.

<<Data Communication Signal Embodied in Carrier
20 Wave>>

Furthermore, the above program can be stored in the hard disk and the memory of the computer, and downloaded to other computers via communication media. In this case, the program is transmitted as data communication signals
25 embodied in carrier waves via the communication media. Then, the computer downloaded with this program can be made to function as the Web server 1 or the receipt mail

server 2 in the embodiments discussed above.

Herein, the communication media may be any one of cable communication mediums such as metallic cables including a coaxial cable and a twisted pair cable, optical
5 communication cables, or wireless communication media such as satellite communications, ground wave wireless communications, wireless LANs, Bluetooth, etc..

Further, the carrier waves are electromagnetic waves for modulating the data communication signals, or the light.
10 The carrier waves may, however, be DC signals. In this case, the data communication signal takes a base band waveform with no carrier wave. Accordingly, the data communication signal embodied in the carrier wave may be any one of a modulated broadband signal and an unmodulated
15 base band signal (corresponding to a case of setting a DC signal having a voltage of 0 as a carrier wave).

(Industrial Applicability)

The present invention can be applied to an industry
20 of manufacturing and selling information devices, developing programs for the information devices, an industry of system integration including the information devices and an industry of providing services utilizing the information devices.
